ABSTRACT: A formal analytic perturbation expansion in the \(\beta\) term is carried out for the Rossby wave solution of the shallow-water equations in a zonal channel on the \(\beta\)-plane. Apart from a quantization of the meridional wave number, the presence of zonal boundaries alters, to first order, both the velocity and the geopotential structures of the wave but does not alter the phase speed of the wave. The ageostrophic component of the velocity field is identical in first order with that of the unbounded \(\beta\)-plane and is therefore not related to the presence of boundaries. In contrast, the first-order correction to the geostrophic velocity component is inherently related to the presence of walls as it ensures the vanishing of the total meridional velocity on the boundaries. This first-order correction to the geostrophic field yields only a third-order correction in the Rossby phase speed, as can be expected from symmetry considerations. 1. Introduction

The fundamental derivation of Rossby wave propagation on a \(\beta\)-plane was presented originally by Rossby (1939), and has been quoted since in many textbooks, e.g. Gill (1982), Pedlosky (1987), Holton (1992), Cushman-Roisin (1994). In a shallow-water framework, the dispersion relation of Rossby waves of the form

\[
\exp\{i(k_x x - \omega_{Ro} t)\} \exp i k_y y,
\]

becomes (e.g. Gill, 1982)

\[
\omega_{Ro} = -\frac{\beta k_x}{k_x^2 + k_y^2 + (1/R_0)^2},
\]

(1)

(Here \((x, y)\) denotes the Cartesian zonal and meridional directions, \(K = (k_x, k_y)\), is the total wave number and \(R_0 = \sqrt{g/\Omega f_0}\) is the Rossby radius of deformation where \(g\) is gravity and \(H\) is the averaged thickness of the layer of fluid. Furthermore, \(f_0 = 2\Omega \sin \phi_0\) is the Coriolis parameter at a central latitude \(\phi_0\) where \(\Omega\) is the Earth’s angular velocity, \(\beta = 2\Omega \cos \phi_0/R\) is the latitudinal derivative of the Coriolis frequency, evaluated at \(\phi_0\), and \(R\) is the radius of the Earth.)

This elegant result has been derived for an infinite \(\beta\)-plane. As such, it is inconsistent with the approximation of the \(\beta\)-plane (where \(\beta = df/dy\) is constant) which is valid only as long as \(\beta y \ll f_0\) (i.e. \(y \ll f_0/\beta = \tan \phi_0 R\)). Hence, a more consistent set-up (although not necessarily realistic) for Rossby wave propagation on the \(\beta\)-plane is a channel whose zonal walls are located at \(y = \pm L\). Such a channel configuration has been widely used in basic theoretical models for both baroclinic and barotropic instability on a \(\beta\)-plane (e.g. Kuo, 1949, 1973; Charney, 1947; Phillips, 1954; Howard and Drazin, 1964). For rotating annulus experiments which generate topographic Rossby waves, a radial \(\beta\)-plane approximation can be assumed where the radial velocity must vanish on the inner and outer concentric boundaries (e.g. Solomon et al., 1993; Songnian et al., 2001).

On an unbounded \(\beta\)-plane, the structure of the wave consists of geostrophic (denoted by the subscript ‘g’) and ageostrophic (denoted by the subscript ‘a’) velocity components, where the latter is determined by the former:

\[
\mathbf{u}_g = \frac{g}{f_0} \mathbf{z} \times \nabla h,
\]

(2a)

\[
\mathbf{u}_a = \frac{1}{f_0} (i\omega_{Ro} \mathbf{u}_g \times \mathbf{z} - \beta y \mathbf{u}_g).
\]

(2b)

(\(\mathbf{z}\) is the vertical unit vector and \(h\) denotes the time- and space-dependent thickness of the fluid.) The presence of
boundaries requires a straightforward quantization of the meridional wave number to enable the vanishing of the geostrophic meridional velocity there, \(v_g(y = \pm L) = 0\), i.e.

\[
v_g = \tilde{v}_0 e^{i(k_x x - \omega_0 t)} \cos k_y y, \tag{3a}
\]

\[
k_y = \frac{(2n + 1) \pi}{L}, \tag{3b}
\]

where \(n\) is an integer, and only symmetric solutions around \(y = 0\) are considered. This quantization determines also the structure of the ageostrophic velocity, (2b), and thus the \(\beta\) ageostrophic meridional velocity, whose component becomes:

\[
h_0 = \tilde{h}_0 e^{i(k_x x - \omega_0 t)} \cos k_y y, \tag{4a}
\]

\[
\tilde{h}_0 = -\frac{i f_0}{k_x g}, \tag{4b}
\]

and thus the \(O(\beta)\) ageostrophic meridional velocity, whose component becomes:

\[
v_2 = -f_0^{-1} (i \omega \theta_g + \beta y v_g) = -f_0^{-1} \left( \frac{k_y}{k_x} \sin k_y y + \beta y \cos k_y y \right) \tilde{v}_0 e^{i(k_x x - \omega_0 t)}, \tag{5}
\]

does not vanish at the walls. Therefore, the total velocity \(u = u_0 + u_2\), does not satisfy the boundary conditions

\[
v(y = \pm L) = v_g(y = \pm L) + v_2(y = \pm L) = 0,
\]

which implies that quantization of the meridional wave number by itself is insufficient for describing Rossby waves in a zonal channel. Hence, even without baroclinic or barotropic shear, the basic structure and frequency of Rossby waves on a \(\beta\)-plane might be altered due to the presence of zonal boundaries. Thus, in the next section we suggest a more rigorous perturbation scheme for the next order correction to the Rossby waves in a channel that satisfies the no-normal-flow boundary conditions at the walls of a channel on the \(\beta\)-plane.

2. Rossby waves in a zonal channel on the \(\beta\)-plane

The linearized shallow-water equations on the \(\beta\)-plane are (e.g. Gill, 1982):

\[
\dot{u} = (f_0 + \beta y) v - g \frac{\partial h}{\partial x}, \tag{6a}
\]

\[
\dot{v} = -(f_0 + \beta y) u - g \frac{\partial h}{\partial y}, \tag{6b}
\]

\[
\dot{h} = -H \left( \frac{\partial u}{\partial x} + \frac{\partial v}{\partial y} \right), \tag{6c}
\]

where the dot implies the partial time-derivative. Standard quasi-geostrophic approximation of (6) leads then to (1) and (2) for a wavelike solution.

Denoting the small parameter \(\tilde{\beta} = \beta L/f_0 = \cot \phi_0 L/R \ll 1\) (where the last inequality is required by the expansion of \(f(y)\) only to first order in \(y\) throughout the entire channel), then a perturbation expansion in \(\tilde{\beta}\) of the eigenfunctions and eigenfrequency of a zonal wave of the form \(\exp \{i(k_x x - \omega_0 t)\}\), can be written as

\[
\begin{pmatrix}
\mathbf{u} \\
\mathbf{h}/\omega
\end{pmatrix}
= 
\begin{pmatrix}
\mathbf{u}_0 \\
\mathbf{h}_0/\omega_0
\end{pmatrix}
+ \tilde{\beta} \begin{pmatrix}
\mathbf{u}_1 \\

\mathbf{h}_1/\omega_1
\end{pmatrix}
+ \tilde{\beta}^2 \begin{pmatrix}
\mathbf{u}_2 \\

\mathbf{h}_2/\omega_2
\end{pmatrix}
+ \cdots \tag{7}
\]

From the following symmetry argument we expect that the eigenfrequency \(\omega\) should be odd in \(\beta\), i.e. \(\omega_0 = \omega_2 = \ldots = 0\). The system (6) is invariant to a reflection (change of sign) of \(y, v, h, \beta\) and \(\omega\) (i.e. \(t\)). Since the variables \(y, v(y)\) and \(h(y)\) cannot appear in the expression for the eigenvalue \(\omega\), it must have the same symmetry to reflection as \(\beta\), which implies that only odd powers of \(\beta\) appear. Notwithstanding this argument, we leave \(\omega_0\) and \(\omega_2\) in the derivation below and explicitly show that they vanish.

Then the zero-order terms of (6) yields

\[
\begin{pmatrix}
-i \omega_0 \\
-f_0 \\
i k_x g
\end{pmatrix}
\begin{pmatrix}
\mathbf{u}_0 \\
\mathbf{h}_0
\end{pmatrix}
= 
\begin{pmatrix}
0 \\
0
\end{pmatrix}, \tag{8}
\]

where two of the eigensolutions are Poincaré plane waves, whose eigenfrequencies and eigenfunctions are:

\[
\omega_0^{\gamma_{\beta_0}} = f_0^2 + g H K^2, \tag{9a}
\]

\[
\nabla \times \mathbf{u}_0 \cdot \mathbf{z} = f_0 h_0, \tag{9b}
\]

\[
K^2 = k_x^2 + k_y^2, \tag{9c}
\]

and the third (zero frequency) solution yields the steady, geostrophic, solution:

\[
\omega_0 = 0, \mathbf{u}_0 = \left( \frac{g}{f_0} \right) \mathbf{z} \times \nabla h_0. \tag{10a, b}
\]

We focus now on the higher-order corrections (in \(\tilde{\beta}\)) to the geostrophic solution, (10), in the presence of walls. Taking the zonal derivative of (6b), subtracting it from the meridional derivative of (6a) and using (6c) we obtain the potential vorticity equation on the \(\beta\)-plane:

\[
\frac{\partial}{\partial t} \left[ \frac{1}{f_0} \left( \frac{\partial v}{\partial x} - \frac{\partial u}{\partial y} \right) - \left( 1 + \beta y \right) \frac{h}{L} \right]
= -\tilde{\beta} \frac{v}{L}, \tag{11}
\]

whose first-order term in \(\tilde{\beta}\), yields \(\omega = \tilde{\beta} \omega_1 = \omega_{\gamma_{\beta_0}}\), where \(\omega_{\gamma_{\beta_0}}\) is defined in (1). In order to find the first-order structure of the bounded Rossby waves, we take the second-order term, \(O(\tilde{\beta}^2)\), of (11):

\[
\begin{align*}
\omega_1 & \left[ \frac{1}{f_0} \left( \frac{\partial v_0}{\partial x} - \frac{\partial u_0}{\partial y} \right) - \frac{h_0}{H} \right] \\
+ \omega_1 & \left[ \frac{1}{f_0} \left( \frac{\partial v_1}{\partial x} - \frac{\partial u_1}{\partial y} \right) - \frac{h_1}{H} - \frac{y}{L} \frac{h_0}{H} \right] + i \nu_1 = 0.
\end{align*} \tag{12}
\]
Using (1) and $\tilde{\omega}v_1 = \omega_{\nu_0}$, together with (10b) we get from (12):

$$\frac{\omega_2}{\omega_1}g k_x h_0 + \omega_1L \left\{ \frac{1}{f_0} \left( i k_x v_1 - \frac{\partial u_1}{\partial y} \right) - \frac{h_1}{H} - \frac{y}{L} h_0 \right\} + i \nu_1 = 0. \quad (13)$$

Next we wish to find an equation for $v_1$ as a function of $v_0$ only. Towards this end, we first take the $O(\tilde{\beta})$ term of (6a) which together with (10) yields:

$$h_1 = -\frac{if_0}{g k_x}v_1 + \left( y - \frac{y k_x \omega_1}{k_x f_0} \right) h_0. \quad (14)$$

The meridional derivative of the $O(\tilde{\beta})$ term of (6c) yields:

$$\frac{\partial h_1}{\partial y} = \frac{i}{k_x} \left\{ k_x \omega_1 \frac{h_0}{H} + \frac{\partial^2 v_1}{\partial y^2} \right\} \hat{e}_0 e^{ik_0(x-\omega_{\nu_0}t)}. \quad (15)$$

Now, substituting $h_1$ and $\partial h_1/\partial y$ back into (13) and writing $h_0 = -(f_0/gk_x)v_0$ (cf. 10b), we finally obtain a linear inhomogeneous differential equation for $v_1(y)$ where the inhomogeneous part is proportional to $v_0(y)$:

$$\left( \frac{\partial^2}{\partial y^2} + k_y^2 \right) v_1 = \frac{1}{L} \left( 2 \frac{f_0^2}{gH} y - k_x f_0 \frac{\omega_2}{\omega_1^2} \right) v_0. \quad (16)$$

The zero-order solution for $v_0(y)$ that satisfies the boundary conditions at $y = \pm L$ is given by (3a) with $k_x$ quantized as in (3b). The fact that $v_0(y)$ is a solution of the homogeneous equation associated with (16), together with the presence of a $y v_0(y)$ term in the inhomogeneous part of (16), implies that the general solution of $v_1$ is

$$v_1 = \left\{ (ay^2 + by + c) \cos k_y y + (dy^2 + ey + f) \sin k_y y \right\} \hat{e}_0 e^{ik_0(x-\omega_{\nu_0}t)}, \quad (17)$$

where $(a, ..., f)$ are some yet undetermined constants. The coefficient $c$ may be absorbed in the zero-order solution and we therefore set it to zero. Evaluating the left-hand side of (16) for this form of $v_1(y)$ yields

$$\left( \frac{\partial^2}{\partial y^2} + k_y^2 \right) v_1 = \left\{ 4k_y y (d \cos k_y y - a \sin k_y y) + 2(a + k_x e) \cos k_y y + 2(d - k_x b) \sin k_y y \right\} \hat{e}_0 e^{ik_0(x-\omega_{\nu_0}t)}. \quad (18)$$

Substituting (18) in the left-hand side of (16) fixes the coefficients $a, b, d, e$. Since $a = 0, e \propto \omega_2$. The boundary conditions $v_1(y = \pm L) = 0$ fix $e$ and $f$. Specifically $e = 0$ and therefore $\omega_2 = 0$ as expected. We finally obtain

$$v_1 = \frac{1}{2Lk_y^2 gH} \left\{ y \cos k_y y + k_y (y^2 - L^2) \sin k_y y \right\} \hat{e}_0 e^{ik_0(x-\omega_{\nu_0}t)}. \quad (19)$$

Hence, while for this order of $\tilde{\beta}$ the boundaries do not affect the phase speed of the Rossby wave, they do alter the eigenfunction by adding first-order terms in $\tilde{\beta}$ to the eigenfunctions. In order to express the first-order correction ($u_1, v_1, h_1$) in terms of the zero-order height (stream function),

$$h_0 = \hat{h}_0 \cos k_y y \exp \{ i(k_x x - \omega_{\nu_0}t) \},$$

we use the $O(\tilde{\beta})$ terms of (6b), (6c) and (14) to get

$$u_1 = \frac{f_0}{2L} \left[ \left( \frac{2}{k_x f_0} - k_y^2 - (y^2 - L^2) \right) \cos k_y y 
\right. \left. - \frac{y}{k_y} \sin k_y y \right] \hat{h}_0 e^{i(k_x x - \omega_{\nu_0}t)}, \quad (20a)$$

$$v_1 = \frac{i f_0 k_x}{2Lk_y} \left\{ y \cos k_y y + k_y (y^2 - L^2) \sin k_y y \right\} \times \hat{h}_0 e^{i(k_x x - \omega_{\nu_0}t)}, \quad (20b)$$

$$h_1 = \left\{ \frac{y}{L} \left( 1 + \frac{f_0^2}{gH} \frac{1}{2L^2} \right) \cos k_y y \right. \left. + \left( \frac{f_0}{gH} \frac{y^2 - L^2}{2Lk_y} + \frac{k_x \omega_1}{k_x f_0} \right) \sin k_y y \right\} \hat{h}_0 e^{i(k_x x - \omega_{\nu_0}t)}. \quad (20c)$$

We now wish to understand why the modification in the eigenfunctions of $(u, h)$, induced by the zonal boundary conditions, is not accompanied by changes in the Rossby wave frequency, $\omega_{\nu_0}$. Hence, decomposing the first-order velocity into its geostrophic and ageostrophic components, i.e.

$$u_1 = u_{1a} + u_{1g}, \quad \text{where} \quad u_{1g} = \frac{g}{f_0} z \times \nabla h_1,$$

then the first-order terms in (6) become

$$-i \omega_1 u_0 = f_0 \left( \frac{u_{1a} + \frac{y}{L} v_0} {v_0} \right), \quad (21a)$$

$$i \omega_1 v_0 = f_0 \left( \frac{u_{1a} + \frac{y}{L} u_0} {u_0} \right), \quad (21b)$$

$$-i \omega_1 h_0 = -H \left( \frac{\partial u_{1a}}{\partial x} + \frac{\partial v_{1a}}{\partial y} \right). \quad (21c)$$

Subtracting the geostrophic component $(u_{1a}, v_{1a})$ from (20a,b), respectively, we find that

$$u_{1a} = -\frac{f_0}{g} \left[ k_x \omega_1 \cos k_y y + \frac{f_0}{L} k_y y \sin k_y y \right] \hat{h}_0 e^{i(k_x x - \omega_{\nu_0}t)}, \quad (22a)$$

$$v_{1a} = -\frac{i f_0}{g} \left[ k_x \omega_1 \sin k_y y + \frac{f_0}{L} k_y y \cos k_y y \right] \hat{h}_0 e^{i(k_x x - \omega_{\nu_0}t)}. \quad (22b)$$
Hence $\mathbf{u}_{1a} = f_0^{-1}(i\omega_R \mathbf{u}_{g0} \times \mathbf{z} - \beta y \mathbf{u}_{g0})$ exactly equals the first-order ageostrophic component of the unbounded Rossby waves given in (2b). Since (21) indicates that only the ageostrophic component of the first-order eigenfunction is involved in the Rossby wave dynamics, the role of the geostrophic first-order component is 'only' to ensure the vanishing of the total meridional velocity component on the boundaries.

We finally wish to examine how the boundaries alter the structure of the velocity and the geopotential distribution of the Rossby wave. In Figures 1 and 2, we plot some of the velocity and geopotential fields for typical values of $f_0 = 10^{-4} \text{s}^{-1}$, $g = 10 \text{ ms}^{-2}$, $H = 10 \text{ km}$, $L = 10^6 \text{ m}$, and $(k_x, k_y) = \pi/2L(1, 3)$ which implies $\tilde{\beta} \approx 0.165$. In Figure 1 the first-order ageostrophic velocity vector field $\mathbf{u}_{1a}$, as obtained from (2b) or (22), versus the zero-order geopotential anomaly $h_0$, as obtained from (4), are plotted. Positive and negative values of $h_0$ are indicated respectively by solid and dashed contours. The structures of both $\mathbf{u}_{1a}$ and $h_0$ remain unchanged for both the unbounded and bounded $\beta$-plane configurations. Hence, Figure 1 represents the classical wave structure obtained by Rossby (1939). It is clear both from the plot and from (5) that the ageostrophic meridional velocity $v_{1a}$ does not vanish at the channels walls ($y = \pm L$).

While (21c) indicates that the divergence field is located $\pi/2$ out of phase to the west of the negative zero-order geopotential anomaly $h_0$, it is difficult, however, to deduce the divergence field of $\mathbf{u}_{za}$, directly from Figure 1. The reason for this is that $\mathbf{u}_{1a}$ is both rotational (its vorticity is mainly opposing the zero order geostrophic vorticity) and divergent. The largest term in the expression of the divergence is

$$
\left(\frac{\beta y}{f_0}\right) k_x \sin(k_y y/2L) \exp\{i(k_x x - \omega_R t)\}
$$

that appears in opposite signs in $\partial u_{1a}/\partial x$ and $\partial v_{1a}/\partial y$, cf. (22). Thus, an estimate of the divergence from

![Figure 1](https://www.interscience.wiley.com/qj/)

Figure 1. The first-order ageostrophic velocity vector field $\mathbf{u}_{1a}$ (arrows) as obtained from (22), and the zero-order geopotential anomaly $h_0$ as obtained from (4) (with positive and negative values indicated by solid and dashed contours respectively). Here and in Figure 2 we take a channel of meridional width $2L$, where $L = 10^6 \text{ m}$. Values of the other variables are given in the text. This figure is available in colour online at www.interscience.wiley.com/qj
3. Concluding remarks

This short note refers to the inconsistency in the concept of ‘infinite β-plane’ which underlies the original quasi-geostrophic derivation of Rossby (1939), where on the one hand a finite meridional extension is required \( y \ll f_0/\beta \), while on the other hand the boundaries are set at \( y = \pm \infty \).

The analysis presented here provides the \( O(\tilde{\beta}) \) correction to the geostrophic velocity for Rossby waves in a zonal channel on the β-plane. The solution satisfies both the equation and the boundary condition, in contrast to the classical theory on the unbounded β-plane where the \( O(\tilde{\beta}) \) correction describes only the ageostrophic part of the velocity field. The ageostrophic first-order correction to the solution remains unchanged when the infinite β-plane configuration is bounded by a zonal channel. Since only the ageostrophic component of the first-order eigenfunction is involved in the Rossby wave dynamics, this yields the \( O(\tilde{\beta}^2) \) correction to the wave phase speed to vanish identically, a fact that can actually be anticipated based on the symmetry properties of the governing equations. Hence, the geostrophic first-order component does not take an ‘active role’ in the first-order dynamics of the Rossby waves (it can be shown that it affects the third-order correction of the phase speed), and in a sense acts to ensure the vanishing of the total meridional velocity component on the boundaries.

The main effect of the boundaries on the Rossby wave is therefore on its meridional structure. The first-order correction distorts the meridional wave-like structure by enhancing the geopotential anomaly on the north and suppressing it on the south of the channel. In contrast, the velocity field, together with the vorticity field, is shifted southwards. The obtained meridional asymmetry (especially the geopotential meridional asymmetry) is in general agreement with the much more sophisticated analysis, performed by Panayotova and Swanson (2006),
of the edge wave asymmetries obtained in a baroclinic channel. While the latter reveals many other aspects of asymmetry (their analysis was based on the QG+ framework, established by Muraki et al. (1999), and included the effect of a zonal jet), our much more modest analysis suggests that a meridional shift of Rossby waves on a β-plane is inherent in the presence of zonal boundaries and should be taken into account when a zonal channel β-plane model is being implied.
